

**Abstract**

The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. The study included 600 male employees from a large manufacturing company. Data were collected through self-administered questionnaires. The results showed that the prevalence of musculoskeletal disorders was higher among manual workers compared to non-manual workers. The most common disorders were low back pain and neck pain. The study also found that age and duration of employment were significant factors associated with the prevalence of musculoskeletal disorders.
